

**SYNERGISTIC STABILIZER COMPOSITIONS COMPRISING COPOLYMERS OF
ETHYLENE WITH HINDERED AMINE MOIETIES CONTAINING ACRYLATE- OR
METHACRYLATE COMONOMERS**

5 BACKGROUND OF THE INVENTION

The invention relates to synergistic stabilizer compositions comprising copolymers of ethylene with hindered amine moieties containing acrylate- or methacrylate comonomers and other light stabilizers for polymer articles.

- 10 The demand for increasingly versatile plastic materials has promoted their penetration in a variety of application areas where it is required to provide increasing durability of effective stabilization. Antioxidants have to retard or to prevent degrading reactions within the polymer matrix which involves many competing reactions. But decreasing polymer protection due to a loss or decomposition of stabilizers is often observed. Since
- 15 the early beginnings of the use of antioxidants such as sterically hindered phenols and amines a move from low molecular weight products to higher molecular weight products can be observed. Reason for those changes was to develop stabilizers with higher leaching resistance and reduced tendency of diffusion out of the polymer matrix. In a subsequent step stabilizers have been prepared with varying degrees of success which
- 20 can be covalently bound to the polymer chain. Nevertheless considerable improvements of the extraction resistance of such bound stabilizer moiety can be reached but the performance is often sacrificed.

- Developments with modified focus were based and base on physical blends of
- 25 stabilizers in order to take advantage of their homo- or heterosynergistic efficiency. This could be reached if a blend-composition of two stabilizers – for example two sterically hindered amine stabilizers (HAS) or HAS with UV-absorbers (UVA) - shows a higher contribution as compared to the individual components.

- 30 As polymer materials move into new application areas such as food packaging or even medical devices, numerous regulations were set up by the authorities governing these specific applications. Obviously polymer-bound stabilizers should be able to prevent undesired food contamination and to maintain a long service life, high transparency and exceptional resistance to chemical attack. Likewise in multilayer products migration of
- 35 stabilizers from one layer to another can remove the stabilizer from most oxidation-sensitive domains of the polymer device.

An additional objective for polymer bound stabilizers are uncontrolled changes of polymer surface properties. In some cases this effect can be connected with the loss of cling, sealing or printability features which affects parameters such as peel strength and adhesion to the base material.

Technical requirements for plastic articles used in outdoor applications such as agricultural films and geotextiles are high. Those articles must resist weathering due to sunlight, humid conditions and chemicals. State of the art are Ni-quenchers and benzophenone-based UVA's, HAS and particularly higher molecular weight tertiary HAS systems which offer an efficient approach to UV-stabilization. Future market needs focus on longer lived and thinner articles e.g. films which requires even more powerful, migration-resistant stabilizers.

SUMMARY OF THE INVENTION

It has now been found that combinations of a random copolymer of ethylene and hindered amine moieties containing acrylates/methacrylates with light stabilizing components based on sterically hindered amines (HAS) and/or UV-absorbers (UVA) in a variety of different polymer substrates lead to a pronounced synergistic stabilization effect. Such effects have been found in all kinds of polyethylene and ethylene-based copolymers which are used in a broad variety of polymer geometry's (thin films, thick sections, fibers etc.).

DESCRIPTION OF THE PREFERRED EMBODIMENTS

Object of the instant invention are synergistic stabilizer compositions for thermoplastic polymers comprising

- a) a random copolymer of ethylene (I) and hindered amine moieties containing acrylates/ methacrylates (II)

and

- 5 b) at least one light stabilizing compound based on sterically hindered amines (HAS) and/or UV absorbers,

wherein

- 10 R1 and R2 are each an independent hydrogen atom or a methyl group,
 R3 is a hydrogen atom, a C₁-C₄-alkyl or a C₁-C₈-alkoxy group,
 the ratio of component (II) to the sum of components (I) and (II) is less than 2 mol-%,
 and
 the weight ratio of component a) to component b) is from 100:1 to 3:1, preferably from
 15 20:1 to 5:1.

Preferably R1, R2 and R3 are hydrogen.

- 20 When the light stabilizing compound b) is propanedioic acid,[(4-methoxyphenyl)-methylene]-,bis(1,2,2,6,6-pentamethyl-4-piperidiny)ester (compound (III))

a high synergistic effect is observed.

The product out of components (I) and (II) (component a)) represents a random
 5 copolymer with a melt flow ratio ranging from 0.1 to 200 g/10 minutes (definition see EP-A-0 468 418).

The copolymer itself is known from EP-A-0 468 418, US 5,182,349 and US 5,262,233.

- 10 Synergistic systems consisting of the here claimed copolymers of ethylene and hindered amine containing moieties of acrylates/ methacrylates with other HAS-based stabilizers and / or UV-absorbers offer clear advantages with regard to sophisticated technical requirements (several years outdoor performance, maximum transparency, no loss of [visible] light transmission, high thermicity, minimum dust accumulation, chemical
 15 resistance, anti-fogging properties etc.).

Particularly advantageous is the use of said synergistic compositions for those polymeric, mostly polyethylene-based, articles which are exposed to permanent extraction and aggressive and/or hazardous chemicals.

20

Significant technical parameters such as carbonyl formation or time to brittleness under accelerated conditions reflecting the lifetime of the corresponding polymer article under ambient conditions can be significantly improved against the state of the art by said

compositions.

The magnitude of these effects is particularly surprising in the light of the literature. For example, HAS-systems linked to the matrix polymers result in much poorer weathering
 5 performance [J.L.Hahnfeld and D.D.Devore, Polym. Degrad. Stab., 39, 241 (1993)]. This drawback is not obvious since the HAS moiety is still active but just fixed by a covalent bond to the polymer chain.

Even more surprising is the high specific efficiency of the used HAS-grafted copolymers
 10 of type I/II despite its relatively low concentration of active HAS-functionality (about 5 wg-%) compared to conventional, oligomeric HAS-compounds such as compound (B) or compound (D) (see examples).

A further object of the instant invention therefore is a method of use of said stabilizer
 15 compositions for the stabilization of thermoplastic polymers, especially polyolefins, in concentrations of 0.5 % to 20 %, preferably 1.0 % to 10 % by weight, based on the polymer.

Another object of the instant invention is a process of stabilizing thermoplastic polymers,
 20 especially polyolefins, by incorporating 0.5 % to 20%, preferably 1.0 % to 10 % by weight, based on the polymer, of said stabilizer compositions.

Aⁿ is an anion of valence n

n is an integer from 1 - 4

x is a value between 0 and 0.5

PREPARATION AND TESTING OF BLOWN PE-LD-FILMS

Blown films of PE-LD [type Lacqtene FB 3010, mfi: 0.3 (190 °C/2.16 kg); producer: Elf Atochem; base stabilization 0.005 % compound (J)]. The individual additional stabilizer formulations have been incorporated into the substrate using a mixer. Auxiliary additives
10 have been dissolved in acetone for even distribution in the polymer and the solvent has been evaporated subsequently in the vacuum at 50 °C/30 min..

15

Afterwards, the different mixtures have been pre-extruded using a single screw extruder at 60 rpm with a die of 3 mm diameter at a melt (bulk) temperature T=180 °C.

Films of the thickness 100 µm were then prepared using a blow molding unit, type Collin with a temperature profile in the range of T= 160-180 °C at a screw speed of 35 rpm. The blow head was heated up to T=195 °C. The final film was drawn at an extracting speed of 1m/min. Pieces of the size 35 x 65 mm were cut for WOM-exposure and/or
20 later treatment with a solution of the insecticide Permethrine P 25/75.

For acid exposure tests pieces of the size 40 x 40 mm have been cut out.

The samples for insecticide treatment were placed on metal supports as used for
25 weathering tests and exposed to UV-light according to CAM-7 conditions (DIN 53 387/A) in a weatherometer type Atlas WOM 65. Every two weeks the samples have been placed for 24 hours in a methanolic solution containing 0.15 wg-% of the insecticide Permethrine P25/75, washed with demineralized water and dried at room temperature prior to re-continued WOM-exposure.

30

Samples used for alternating UV-exposure and acid treatment fixed in frames were exposed to UV-light according to CAM-7 conditions as described above. Every week the

samples have been dipped during 24 hours in an aqueous sulfurous acid (concentration 0.1 mol/l), washed with demineralized water and dried at room temperature.

The time to brittleness was determined by 180° mechanical bending of the film. The results are presented in tables 1-3.

10 **STABILIZATION OF BLOWN PE-HD-FILMS AGAINST LIGHT EXPOSURE**

- Blown films (thickness 50 μm) by mixing powdered PE-HD (type TVK FB 472; producer TVK, Hungary; mfi (unstabilized) 0.8 g/10 min. (190°C/2.16 kg); initial cristallinity 58%) with the required additives in a laboratory mixer, type Kenwood. Pre-extrusion with the individual formulations took place twice at 200°C using a single screw extruder type
- 15 Collin with a screw composition 1:3, die diameter 3mm, screw speed 80 rpm before film blowing was carried out at 220°C using an extruder, type Collin with a film blowing unit. The received films have been transferred within diapositive-frames consisting of a plastic material in a wheather-o-meter type 65 WRC (producer Atlas) equipped with a Xenon lamp (6.5 kWatt) allowing an irradiation energy of 0.33 W/m² and with inner and
- 20 outer filters based on borosilicate S. For artificial exposure the program CAM-7 (according ISO 11341) was chosen frequently applying 2 different wheathering phases: in a first phase (duration 102 minutes) under "dry" conditions (50% rel. humidity) a black

panel temperature of 63 °C was adjusted whereas in a second period (duration 18 minutes) a black panel temperature of 50°C was set keeping the samples under 90% rel. humidity. The end of the experiment was reached for each individual sample as soon as brittleness was observed. The results for the series of non pre-treated samples are given in table 4. Prior to exposure in the weather-o-meter another series of samples have been dipped for 24 hours at room temperature in a 0.1molar aqueous sulfurous acid solution before the artificial weathering program as described above took place. The data of this series are presented in table 5.
